The OpenMP programming model is defined by an open standard and has well-defined bindings to the Fortran and C/C++ programming languages. OpenMP versions 2.0 and 2.5, which are supported by the Microsoft C++ compiler, are well-suited for parallel algorithms that are iterative; that is, they perform parallel iteration over an array of data.

Concurrent and parallel programming languages involve multiple timelines. Such languages provide synchronization constructs whose behavior is defined by a parallel execution model. A concurrent programming language is defined as one which uses the concept of simultaneously executing processes or threads of execution as a means of structuring a program. A parallel language is able to express programs that are executable on more than one processor.

OpenMP represents a collection of compiler directives, library routines and environment variables meant for parallel programming in shared-memory machines. A chapter is going to be devoted to each of these elements, but before starting with the review of the available compiler directives, it is necessary to have a look at some basic aspects of OpenMP.

OpenMP is a particularly simple parallel programming notation. It works on shared-memory computers. This means you can work with tasks without the need to explicitly decompose your data. However, this also means you can easily create a program with accidental data sharing which can lead to the race conditions we discussed in part 3.

and models have been proposed in the past several decades [Mattson, 2004]. The ones that are the most widely used are message passing interface (MPI) [MPI 2009] for scalable cluster computing, and OpenMP [Open 2005] for shared memory multiprocessor systems. Both have become standardized programming interfaces supported by major computer vendors.
