It is normal to use specific properties so the equation becomes $Tds = du + pdv$. but from the gas law $pv = RT$ we may substitute for p and the equation becomes $Tds = du + RTdv/v$. rearranging and substituting $du = cvdT$ we have. $ds = cvdT/T + Rdv/v$(1) s is specific entropy.

Introduction to Compressible Flow

Compressible flow (or gas dynamics) is the branch of fluid mechanics that deals with flows having significant changes in fluid density. While all flows are compressible, flows are usually treated as being incompressible when the Mach number (the ratio of the speed of the flow to the speed of sound) is greater than 0.3 (since the density change due to velocity is about 5% in that case).

Compressible flow - Wikipedia

A numerical solution method is developed for the solution of two-dimensional, irrotational and compressible fluid flow problems. The partial differential equation, in terms of the velocity potential, describing the flow is replaced by finite difference equations and the resulting matrix is solved by Gaussian elimination.

The numerical solution of two-dimensional fluid flow problems

$d^2 f/dz^2 + R f^2 = ?$; $f(?1) = f(1) = 0.$ $\{\displaystyle \{\frac {d^ {2}f} {dz^ {2}}\}+Rf^ {2}=-1;\quad f (-1)=f (1)=0.\}$ This ordinary differential equation is what is obtained when the Navier-Stokes equations are written and the flow assumptions applied (additionally, the pressure gradient is solved for).

However, for compressible flows, since the density is not constant, the equations of continuity, momentum and energy conservation have to be considered simultaneously in order to obtain a solution to a flow problem. In reality, every fluid is compressible.
